## 1 Introduction

The objective of this document is to establish a database that represents the status quo in the following fields:

- Seaplane aircraft & manufacturers
- Seaplane operators
- Seaplane organizations
- Sea dromes

Used sources were the aircraft compendium Jane's All the World's Aircraft (Jane's Information Group, 2003) and several sources on the internet. Although there is considerable activity in the field of ultra-light seaplanes, the focus in this document is on transport aircraft.

The identification of the State-of-the-Art of seaplane operations worldwide is a critical part of WP1. Historical data about seaplane and amphibian aircraft and types of operation was found useless for investigations about the current transport system as aircraft models have mainly been designed for military purposes before and during World War II.

To get an overview about the current application of seaplanes and amphibians, a thorough investigation of active operators and aircraft used was undertaken using their internet presences as well as the national registration databases. Additionally an online survey has been created and made accessible to operators worldwide on the project website.

The following topics have been identified as subject of interest for the survey:

- General Information about Seaplane Operators
- Operational Issues
- Pilots, Regulations and Certification
- Infrastructure and Aircraft
- General issues and comments on the future development of the seaplane transport system.

Over 300 operators were asked to participate in the survey. It was unclear from the list, which of the companies are still operating especially as the invitations

were sent out in winter 2009, still in the wake of the world financial crisis. With 28 participants it is hence also unclear which percentage of the active operators was covered.

## 2 Aircraft

### 2.1 Aircraft Manufacturers

Table 1 gives an overview of the currently active manufacturers of seaplanes or amphibians. Also companies who have not yet started manufacturing or obtained a type certificate are included.

Table 1: List of aircraft manufacturers

Within the list of aircraft discussed in the following sections, it will be shown that the models of former Canadian manufacturers De Havilland Canada (DHC) and Canadair are among the most frequently used. The type certificates of the company are nowadays owned by Viking Air and Bombardier respectively. The general

impression given by the list of manufacturers clearly is that most manufacturers and especially manufacturers with high numbers of aircraft sold are situated in North America.

The situation is very similar for the float manufacturers that are listed in Table 2. Aircraft manufacturers that produce their own floats are excluded. Furthermore, manufacturers of floats for ultra-light or experimental aircraft were not included.

Table 2: List of float manufacturers

## 2.2 Historic Aircraft

For the scope of this document, the term seaplane shall include all aircraft operating on water. The two possible configurations are flying boats, with a shaped fuselage and floatplanes with a conventional body and floats installed as a landing gear. Both configurations can also be equipped with a retractable wheeled landing gear, making the aircraft amphibious

Amphibious Floatplane	Floatplane	Amphibious Flying Boat	Flying Boat
			

Table 3: Types of seaplanes (Ontario Ministry of Natural resources, 2009) (de Havilland Canada DHC-6 Twin Otter, 2007) ([www.luftfahrt.ch](http://www.luftfahrt.ch), 2004) (Dornier Wal, 2008)

In total, 254 aircraft types were found and added to the data base. The complete list of aircraft can be found in Appendix A.

Figure 2-1: Seaplane manufacturing timeline

To evaluate the current situation of seaplane aviation, the first step of processing the data is to create a timeline of aircraft designed and manufactured. Figure 2-1 shows new seaplane designs per year, where the first flight marks the year. It is clearly to be seen, that the height of the seaplanes and amphibians was the pre-World War 2 era. Since then the number of new aircraft stays on a constant low level of one or two mostly very small two- to four-seater models per year. The peak beginning in the early nineteen thirties can be explained with the fact that neither tires for high loads nor a sufficient number of airports were available. Furthermore the missions of the aircraft of that era in the data base include specifically maritime military tasks like coastal defense, and combat with airships and submarines. Taking a look at all the operations performed, given in Figure 2-2, reconnaissance seems to be the most important one followed by passenger transport.

To get an impression of the size of the aircraft in the complete data base, Figure 2-3 shows the percentages if today's certification classes were applied. The bigger part is aircraft with takeoff mass higher than 5670kg that would nowadays be certified under CS-25. With the plain numbers for payload and takeoff mass given in Figure 2-4 and Figure 2-5 it can be seen that there was a tendency to use flying

boats for applications with higher payload and range. It can also be seen that the range of most of the models in the data base stays below 1000nm (1852km).

Figure 2-2: Seaplane mission types

## Certification Classes

Figure 2-3: Seaplane certification classes

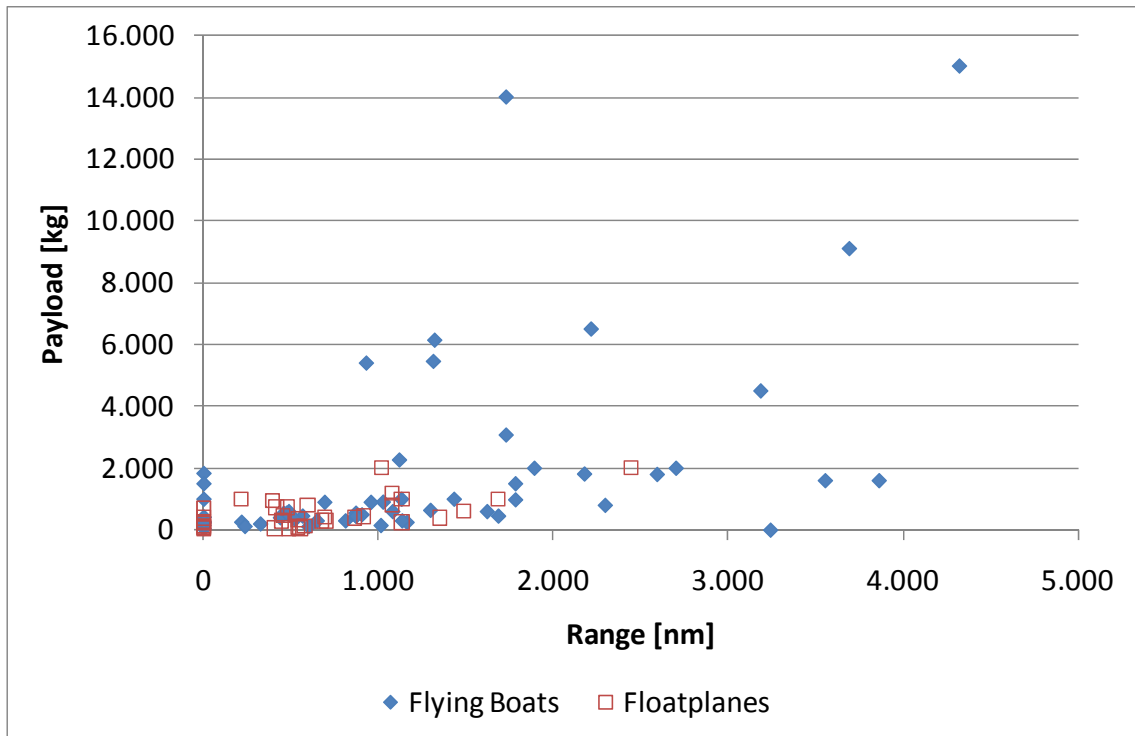

Figure 2-4: Payload and range for historical seaplanes

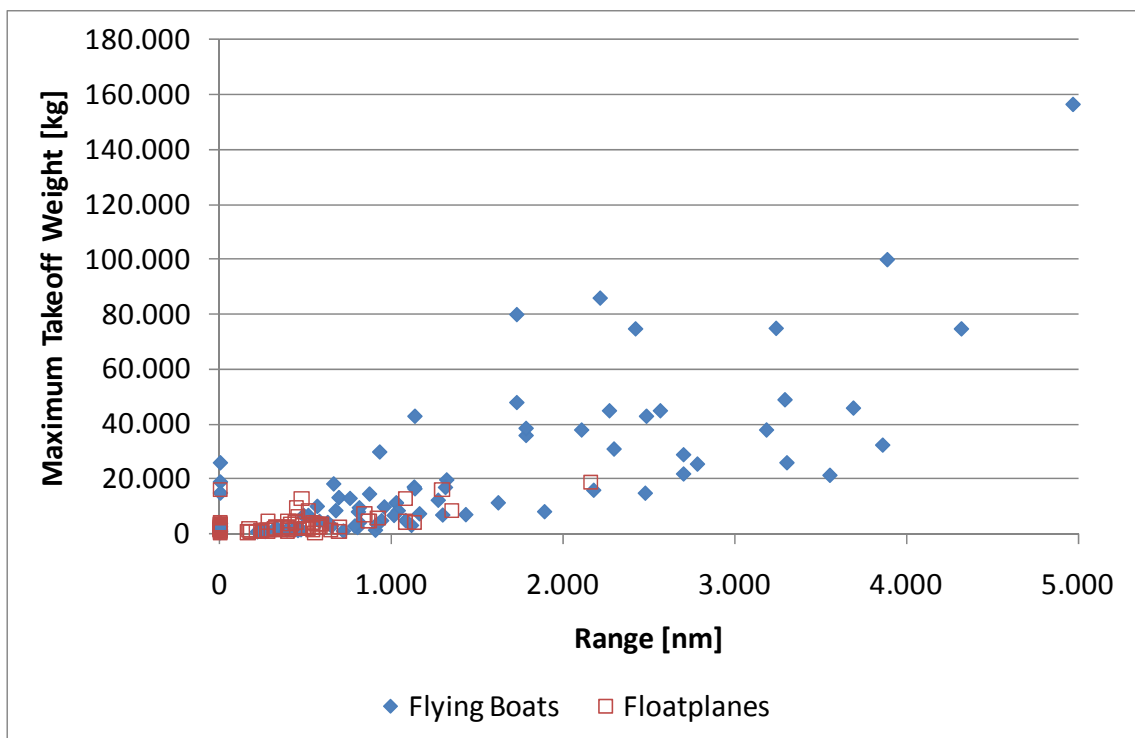

Figure 2-5: Maximum takeoff weight and range for historical seaplanes

## 2.3 Currently operated aircraft

From the historical data collected it is not possible to draw any conclusion about the seaplane transportation system of today. Therefore it has to be clarified which of the aircraft is still operated. This is done by an operator survey as well as with investigations within the national registration data bases and in the internet.

### 2.3.1 Operator survey

Figure 2-6 shows the types and amount of aircraft operated by the survey participants. Furthermore, the fleets of relevant other commercial operators were incorporated into this and the following figures of this section. The overall number of aircraft comprised is 136. The absolute numbers for each aircraft are given in Table 4. It can be seen that distribution of used aircraft is very uneven. For a big part of the models there is only one reported to be in operation. The models of Cessna and especially De Havilland Canada are by far the most popular with the participating operators.

Figure 2-6: Aircraft in Operation

Relating the used aircraft with their passenger capacities given in Table 4 leads to the percentages of different sizes of aircraft given in Figure 2-7. Contrary to the statement on size given in Figure 2-3, all used aircraft could be certified under CS-

23. The biggest percentage of aircraft is in the range from seven to nineteen passengers.

	<b>Amount</b>	<b>PAX</b>
Aviat Husky	1	1
Beech C23	1	3
Brevity	1	5
Cessna 150	2	1
Cessna 172	9	3
Cessna 180	5	4
Cessna 182 Skylane	1	3
Cessna 185	2	5
Cessna 206	7	5
Cessna 208 Caravan	7	9
DHC-2 Beaver	36	7
DHC-3 Otter	27	11
DHC-6 Twin-Otter	52	19
Grumman HU-16	1	19
Maule M-7	1	3
Piper PA18	1	1
Taylorcraft BC12D	1	1

Table 4: Aircraft capacities and amount in use by survey participants

Figure 2-7: Size of aircraft in operation

For all the aircraft collected, the percentages of the used type of undercarriage or seaplane type are shown in Figure 2-8. It can be seen that the floatplane is almost the only relevant type of seaplane currently operated. The one percent of flying boats solely consists of the historic Grumman HU-16 used for the scenic flights and the portion of conventional landing gears is included because operators mixed seaplane/landplane fleet included all aircraft in the survey.

Figure 2-8: Undercarriage types

### 2.3.2 Restrictions because of availability of suitable aircraft

Operators were asked if they see the growth of a future seaplane transport system being restricted by the availability of suitable aircraft. At least 41% answered YES to this question. The year of first manufacturing of most seaplanes in operation has been several decades ago and the wish for efficient new aircraft is rising. Operators indicate the will to participate in the definition of requirements towards new aircraft in future FUSETRA surveys.

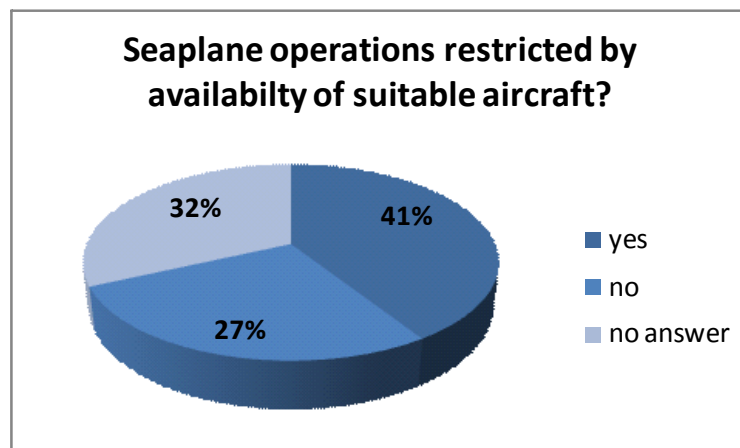

Figure 2-9 Restrictions by available aircraft

### 2.3.3 Future Aircraft Requirements

The main requirements towards future aircraft have been asked, too. The requested payload lies between 250kg and 1500kg for the greatest part of operators. Only few requested larger payloads over 4 tons.

<b>Payload Requirement [kg]</b>	<b>% of operators</b>
<500 kilograms	29%
500-1000 kilograms	29%
1000-1500 kilograms	29%
>1500kg (i.e. 4800kg, 5600kg)	14%

Table 5 Payload requirements

The range requirements are more uniform and show that characteristic stage lengths are far below conventional commercial operations.

<b>Range Requirement [nm]</b>	<b>% of operators</b>
< 250 nautical miles	30%
250- 450 nautical miles	30%
450- 650 nautical miles	20%
650- 850 nautical miles	20%
> 850 nautical miles	0%

Table 6 Range requirements

The required speed for future seaplanes is ranging from 140-180 knots.

Additional comments on features which should be considered in aircraft development in future:

- Capable of operating in open / rough water (good sea state capability)

- High wing
- Amphibian
- IFR capable (Instrument Flight Rules)
- Engine designed to cope with very short cycles in the area of 5/hr
- Hot salt water tolerant resistance
- Good visibility for passengers
- Suitable for use in confined areas
- Suitable for working with boats
- Low operating costs

### 2.4 Registration data base

Registration databases of the National Aviation Authorities (NAA) theoretically offer the possibility to get an overview of the seaplanes currently registered. As stated in 2.3.1, all relevant seaplanes are floatplanes which in all cases means, that there is also a landplane version available. In most of the registration databases unfortunately it is impossible to distinguish between land- and seaplane. Therefore, the most important aircraft described in 2.5 are derived from those that operators identified use. With the importance of online presence nowadays it is very improbable that the internet recherche missed any relevant operators hence any aircraft important for today's seaplane operation.

What is possible with the registration data base is to identify the amount of registered flying boats.

	USA	Canada
Grumman G-21 "Goose"	62	0
Bombardier CL-215/ CL-415	5	58
PBY Catalina	14	0

Table 7: Most numerous flying boats registered in the US and Canada (FAA Registry, 2011)  
(Canadian Civil Aircraft Register, 2011)

The Grumman G-21 and the PBY Catalina are mostly operated by private persons or in very small commercial airlines. The Bombardier CL-215 is a water bomber and almost exclusively registered to governmental organizations related with fire fighting. For the determination of the most important aircraft for aerial firefighting anyway not only the results from registration databases are used but also information on aircraft used by the responsible institutions responsible for firefighting, that are listed in 3.1.

## 2.5 Main characteristics of the most important aircraft

### 2.5.1 Commercial Transport

The most important aircraft in current seaplane operation are displayed in Table 8.

	<b>PAX</b>	<b>Year of first flight</b>	<b>Time of production</b>
Cessna 172 "Skyhawk"	3	1955	1955 - today
Cessna 180	4	1952	1953 - 1981
Cessna 185 "Skywagon II"	5	1960	1961 - 1985
Cessna 206 "Stationair"	5	1964	1965 - today
Cessna 208 "Caravan"	9	1982	1983 - today
DHC-2 "Beaver"	7	1947	1947 - 1967
DHC-3 "Otter"	11	1951	1951 - 1967
DHC-6 "Twin-Otter"	19	1965	1965 - 1998; 2008 - today
Quest Kodiak	10	2004	2007 - today

Table 8: Most important transport aircraft

All the listed aircraft are floatplanes. None of the floats are retractable which means that a lot of performance losses are created due to the additional undercarriage drag. Also it has to be noted that the newest of the aircraft is the Cessna 208 which is already 30 years old. Although updates with new turbine engines or parts of the aircraft made out of composite materials exist, especially the fact that the biggest part of the aircraft is made of metal is a very big problem for waterborne operation. Protection from corrosion requires a maintenance effort incomparably higher than for landplanes.

	<b>Cessna 172</b>	<b>Cessna 180</b>	<b>Cessna 185</b>	<b>Cessna 206</b>	<b>Cessna 208</b>

Table 10: Technical data of DeHavilland or Viking Air aircraft (Jane's Information Group, 2003)

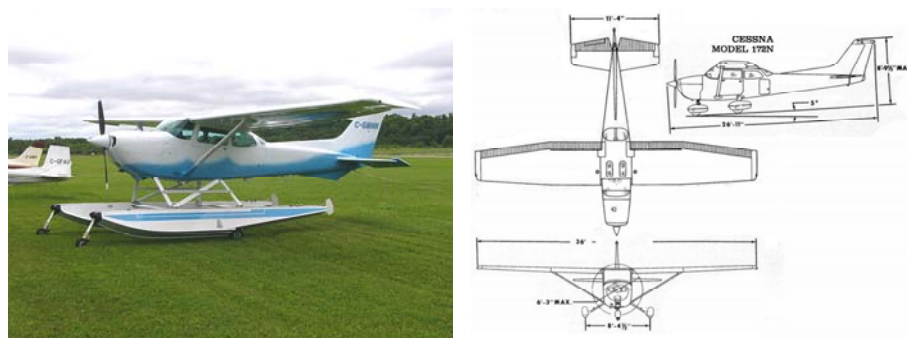

Figure 2-10: Photo and 3-view of the Cessna 172 (Cessna 172, 2008) (Cessna 172,n.d.)

Figure 2-11: Photo and 3-view of the Cessna 185 (Cessna 185, 2006) (3 View Aircraft –Index Directory, n.d.)

Figure 2-12: Photo and 3-view of the Cessna 206 (Cessna 206, 2007)

Figure 2-13: Photo and 3-view of the Cessna 208 (Cessna 208, 2005) (Caravan Amphibian, 2009)

Figure 2-14: Photo and 3-view of the DHC-2 (de Havilland Canada DHC-2 Beaver, 2007)

Figure 2-15: Photo and 3-view of the DHC-3 (de Havilland Canada DHC-3 Otter, 2007)

Figure 2-16: Photo and 3-view of the DHC-6 (de Havilland Canada DHC-6 Twin Otter, 2007)

Reliable detailed data on the aircraft performance is very difficult to obtain, because most are not manufactured anymore. Therefore the losses due to the float installation shall be shown with the example of the Cessna 208. The manufacturer offers payload range diagrams for both the amphibian and the land version that can be seen in Figure 2-17. When comparing the two versions, it is important to know that the landplane version also does not have a retractable landing gear, so performance losses are less obvious than in comparison to an ideal aircraft. From the data of float manufacturers it can be stated that the addition of straight floats adds 439 kg to the aircrafts weight while straight floats only account for 334 kg. The fact that in Figure 2-17 the difference in payload is lower than the weight penalty for the undercarriage installation can be explained with the higher takeoff weight of the amphibian version.

Figure 2-17: Payload-Range diagram for the Cessna 208 version Caravan and Amphibian (Caravan Amphibian, 2009)

Another index to compare the performance of both versions is the cost per mile and hour given by the manufacturer and in Table 11. “The value represents costs for fuel, parts, airframe maintenance, and powerplant maintenance. A fuel cost of \$5.00 per gallon and a shop Rate of \$85.00 per hour is assumed. Actual operating cost will vary according to mission profiles flown, maintenance practices, and utilization.”

	Caravan Amphibian	Caravan 675
Base Price	\$1,886,548	\$1,886,548
Typically-Equipped Price	\$2,357,368	\$2,114,168
Estimated Direct Operating Costs		
Cost per Nautical Mile	\$2.78	\$2.40
Cost per Hour	\$417.40	\$422.40

Table 11: Cost of the Cessna 208 amphibian and landplane version (Caravan Amphibian, 2009)

## 2.5.2 Firefighting

Aircraft mostly operated for aerial firefighting include the Bombardier (former Canadair) CL-215 and its successor the CL-415, the smaller Air Tractor AT-802 Fireboss, and the bigger Beriev Be-200. Their key data is given in Table 12 and Table 13.

	<b>Capacity in [L]</b>	<b>Year of first flight</b>
Bombardier CL-215	4.900	1967
Bombardier CL-415	6.140	1993
Air Tractor AT-802	3.050	1990
Beriev Be-200	11.800	1998

Table 12: Most important aircraft for aerial firefighting (Jane's Information Group, 2003) (Jane's Information Group, 1993)

As to be seen from the data of the firefighting entities given in Table 17, the Bombardier models are by far most widely spread. Contrary to the commercial transport aircraft, the so called water bombers are mostly flying boats, an exception is the Air Tractor AT-802.

Figure 2-18: Air Tractor AT-802 (top left), Beriev Be-200 (top right), Bombardier CL-215 (bottom left) and CL-415 (bottom right) (Air Tractor AT-802, 2009) (Beriev Be-200, 2008) (Canadair CL-215, 2007) (Bombardier 415, 2006)

	<b>CL-215</b>	<b>CL-415</b>	<b>AT-802</b>	<b>Be-200</b>
MTOW [kg]	17.100 (from water) 19.730 (from land)	17.170 (from water) 19.890 (from land)	7.257	37.900 (from water) 41.000 (from land)
Empty Weight [kg]	12.065	12.880	2.951	27.600
Span [m]	28,6	28,6	18,1	32,8
Wing area [m <sup>2</sup> ]	100,3	100	37,25	117,4
Propulsion	2 radial engines (1.566 kW each)	2 turboprop engines (1.775 kW each)	1 turboprop (1.007 kW)	2 turbofans (16.534 lbf each)
Cruise Speed [km/h]	192	333	356	560
Range [km]	2.260	2.443	1.289	2.100

Table 13: Technical data for firefighting seaplanes (Jane's Information Group, 2003) (Jane's Information Group, 1993)

## 2.6 Aircraft currently in development

There are two strategies for providing future seaplanes followed by the manufacturers: Updating of existing models and developing of new ones. Viking Air is the certificate holder for the DHC-2, -2T, -3, -6, -4, -5 and -7 aircraft. They manufacture the DHC-2T and DHC-6-400, where the latter is described as “all new” (Twin Otter – Series 400, n.d.)

Developments that are new from sketch are presented by Dornier Aviation and Centaur seaplane. Both chose the flying boat concept to optimize performance and both are made of composite materials. Dornier has planned an aircraft family called S-Ray. The 2-seater S-Ray 007 has already been flight tested excessively. The transport aircraft S-Ray 008 (8 Pax) and S-Ray 009 (up to 18 Pax) are future

projects. Their data is given in Table 14. In order to give the aircraft high sea stage capability the concept of the Sponsen is used. This design traditionally used by Dornier is a wing stub at low fuselage height. The actual wing is designed as high wing.

	<b>S-Ray 007</b>	<b>S-Ray 008</b>	<b>S-Ray 009</b>
Wing Span [m]	9	17	20
Length [m]	6,9	15,9	16,3
Height [m]	2,2	5,3	5,4
Propulsion	Limbach 2400 DT 100 kW Propeller Sensenich 3 blade	2x Austro Diesel Engine 300 kW each	2x PT6A-65B 820 kW each
Take off distance [m]	120	TBD	840
Landing distance [m]	120	TBD	587
MTOW [kg]	800	4500	8368
Empty weight [kg]	500	1700	4974
Payload [kg]	50	1500	1750 (with 2800 kg fuel)
Operating Speed [km/h]	180	TBD	Max Speed: 358,2
Range	TBD	6 PAX : 2222 Full PL: 1389	Empty: 3189 Full PL: 998

Table 14: Preliminary data of the Dornier S-Ray aircraft family (Wagner, 2010)

The design by Centaur Seaplanes comprises a low stub wing platform with floats at their tips. They planned versions are the Centaur 2 with 2 seats and the Centaur 6

with six or seven seats. For the Centaur 6 there is no data yet. The concept for the Centaur 2 was not yet proven in flight but there is preliminary data available that is available on the company's homepage (Centaur 2 Specifications, 2011)

Figure 2-19: Dornier S-Ray 007 during the flight test campaign (Dornier S-Ray 007,n.d.)

Russian manufacturer Beriev Company has presented plans to extend its range of amphibian aircraft by two models larger than those presented in this section. Both the Be-112 and the Be-114 are intended to be used for passenger and cargo transport, search and rescue and rescue activities and emergency services.

	<b>Be-112</b>	<b>Be-114</b>
Takeoff weight [kg]	11.000	22.000
Payload [kg]	2.350	6.000
Passengers	Up to 27	Up to 44
Propulsion	2 Deagel TVD-1500 turboprop, each 1062 kW	2 Klimov TV7-117 turboprop, each 2088 kW
Maximum speed at an altitude of 3000m [km/h]	420	530
Range [km]	1000	1000
Field length required [m]	850	1300

Table 15: Preliminary data of future Beriev designs (Anon., 2010)

### 3 Operators

#### 3.1 Internet recherche

From an internet recherche, a list of 327 seaplane operators worldwide was gathered. The information in the complete list that is available electronically contains the complete postal address, the web address, phone, fax and email contact data as well as GPS coordinates for the headquarters. An excerpt can be found in Appendix B – Seaplane operators worldwide.

#### Location of Seaplane Operators

Figure 3-1: Location of seaplane operators

The worldwide distribution of seaplane operators in the list, given in Figure 3-1, very impressively shows the dominance of North America. Almost half of all operators are based in the United States, together with Canada it's even bigger than 80%.

The picture is similar when focusing on the biggest operators given in Table 16. Besides two Canadian carriers, including the biggest seaplane operator Harbour Air, there are two Australian companies, two in the USA and two Maldivian carries. Maldivian Air Taxi is the second biggest seaplane operator worldwide. Of the four European operators given, only Harbour Air Malta offers scheduled flights. The sole connection offered is between Valetta on main island Malta to Mgarr on the island Gozo, takes 10min and costs 50€ for an adult one-way ticket. The other operators in Europe, but Harbour Air Malta as well, offer scenic or charter flights. All the operators in Table 16 are commercial. Other seaplane operators like flying clubs, flying schools or private enthusiasts, do not own a relevant number of

aircraft. Exceptions are companies for aerial firefighting. Firefighting also is the task for which public institutions own larger seaplane fleets. From country to country these are the local governments (USA, Canada), the airforce (Croatia, Spain, Greece) or the civil protection or emergency agencies (Italy, Russia, and France). An overview of the entities responsible for aerial firefighting is given in Table 17.

As an example of a bigger commercial seaplane network, the destinations of Harbour Air are given in Figure 3-2. None of the connections offered covers a distance of more than 54 nm (100km). Seaplane operation in this area is that well established, that Kenmore Air and Tofino Air are operating there or in the direct vicinity as well. The concept of Maldivian Air Taxi and Trans Maldivian Aviation is different, as mainly holiday resorts on the different islands are destinations.

There is no information on the use of seaplanes for cargo operations. The allowed luggage varies from operator to operator. For flights with Harbour Air for example, the weight of the luggage is dependent on the connection chosen, but it is never lower than 11,5kg.

	Country of origin	Cessna 172	Cessna 180	Cessna 185	Cessna 206	Cessna 208	DHC-2	DHC-3	DHC-6	Sum

## 3.2 Operator survey

### 3.2.1 General Information about Seaplane Operators

#### 3.2.1.1 Participants' origin

The distribution of survey participants, given in Figure 3-3 and Figure 3-4, shows that around one half them was European, more than one third North American and the rest from India and Australia. The European participants are equally distributed over the continent with slightly more participation in France and the United Kingdom. In Figure 3-4 10% equals one participant. Surprisingly operators from countries with long coast lines, for example from the Iberian Peninsula, the Spanish Isles or Scandinavia (except Norway) did not participate. There are

neither participants from Russia, which is home to a very active seaplane industry and has a lot of inland waterways.

Figure 3-3: Origin of survey participants

Figure 3-4: Origin of European survey participants

### 3.2.1.2 Participants' field of service

The participants' companies or clubs were founded from 1930 to now. Almost two thirds of them were founded in the current decade as to be seen in Figure 3-5. This result strengthens the assumption that a long-lasting seaplane business is very difficult to establish and maintained, but without proven information of former operators it only stays an assumption.

Concerning the services offered by the participants, a general statement has to be made, that most of them offer more than one. The activities are divided into those given in the following list and the results are shown in Figure 3-6.

- Commercial airline
- Commercial airline aspirant (or former commercial airline)
- Flight training
- Flying club
- Manufacturer
- Charter
- Tourist
- Consultant

Popular combinations of services are flying schools that offer charter flights, generally the combination of charter and scenic flights and former commercial airline or aspirants that offer their services as consultants. The manufacturers that participated just provided data about the availability on pilots. Commercial airline aspirants are either working on obtaining their Air Operator Certificate (AOC) or already abandoned this plan.

Figure 3-5: Participants' year of foundation

Figure 3-6: Type of services offered by participants

### 3.2.2 Seaplane operations

#### 3.2.2.1 Operational key figures

To get a picture of the actual all-day performance of the seaplanes in operation, we asked the participants to state on the number of flights per year, the average flight time and distance as well as the average load factor. The results are shown from Figure 3-7 to Figure 3-10. The percentage of participants that provided this type of data is 41%. The numbers gathered for the amount of flights per year unfortunately doesn't allow a clear statement, as the distribution is almost equal. Furthermore there are commercial airlines with a very high number of flight movements, but also those with a very low number. The same phenomenon can be seen for the participants offering flight training, charter and scenic flights. Some have around 40 flights per year while others are above 1200 movements. The highest amount registered is 5000 movements per year.

Figure 3-7: Flights per year and carrier

Figure 3-8: Average load factor

The average load factor worldwide for passenger aviation is around 75%. The average taken from the survey is only slightly higher at 79%. Here a clear tendency can be seen that the load factors of the commercial airlines with fixed schedules are slightly below the average and those of flying schools and for charter and scenic flights are mostly above. This tendency is also to be seen in passenger aviation in general and is easy to be understood from an entrepreneurial view.

Figure 3-9: Average flight time

When comparing the flight times given in Figure 3-9, the only clear result is that the endurance is seldom more than two hours. Again, no clear separation of commercial airlines and the other participants can be done by the flight times.

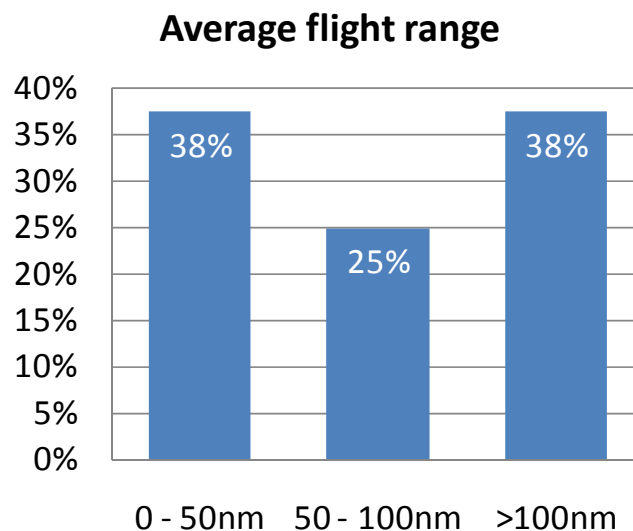

Figure 3-10: Average flight range

The maximum flight range registered is 120nm. The highest values are reported by flying clubs and flying schools, while the average distances of the commercial airlines move between 30 – 70nm. The absolute average is 68nm.

#### 3.2.2.2 Connections and flight plans

Figure 3-11 shows that one quarter of the participants do not operate in winter. Those are mostly those that offer charter and scenic flights, but the main aspect of winter operation is of course the geographic location.

Figure 3-11: Participants' times of operation and schedule structure

Half of the carriers fly only on-demand, 60% mostly. With respect to the flight movements stated, the percentage of on-demand flights is 76%. The scheduled flights are, other than expected, mostly scenic flights. Only one quarter of the participating commercial airlines have a fixed schedule.

The purpose of the flights, with respect to the participants is mostly passenger transportation (including scenic flights), but as to be seen in Figure 3-12, a remarkable portion is declared as other flight. From the services the participants offer, it can be assumed that this is mostly flight training or leisure flights in flying clubs. Fire fighting and cargo transport were offered as flight types in the survey but are only performed by a very low percentage of the participants. Only one participant based in Canada uses his aircraft for firefighting (15% of all flights). Two of the commercial airlines have a very low percentage of cargo transport.

Figure 3-12: Purpose of flight

The results on the question whether the connections are from water to water, from water to land or land connections can be seen in Figure 3-13. When watching them with respect to the participants, more than half are connecting mostly water sites, and this impression is even stronger when relating the results to the number of flights. Then over 80% of all flights are water-to-water connections.

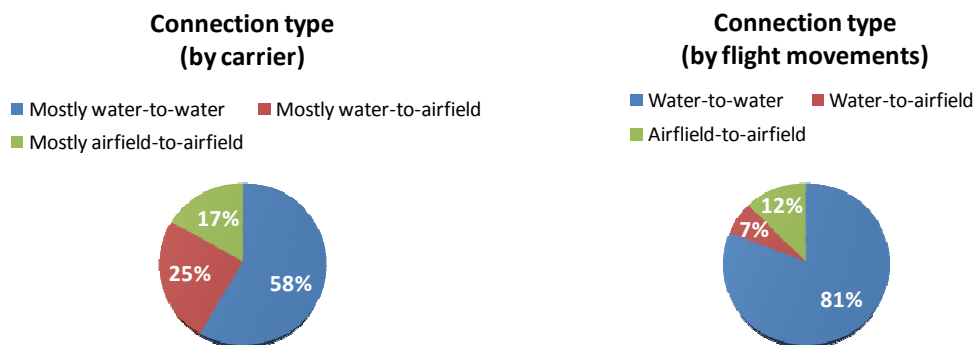

Figure 3-13: Connection type

### 3.2.3 Certification

#### 3.2.3.1 Pilots

The comments on the availability of pilots with seaplane rating are shown in Figure 3-14. The general situation when summarizing all results is not alarming. Almost three quarter of the participants do not characterize the situation as critical. Dividing up the continents shows that in North America the availability of pilots is unproblematic for over 85%, while for two-thirds of the European participants it is critical and challenging for the remaining one-third. In Asia and Australia the situation is generally characterized as challenging.

Figure 3-14: Availability of pilots

It was further asked where the pilots employed with an operator received their original flying license. Without exception it was issued in the country the operator is based in. Free comments on the situation included that mostly North American pilots are available. It was also remarked that even if a pilots are rated for seaplane operation, a big amount lacks sufficient open water experience. A specific problem in the northeast US seems to be that seaplane pilots are only employed seasonally.

#### 3.2.3.2 Operators

All of the participants that answered to the following section of the survey own the aircraft operator certificate (AOC), except for the US based flying schools and the commercial airline aspirants. In all cases it was issued by the national aviation authorities (NAA) of the country the operator is based in. When looking at the participants' description of the certification process in Figure 3-15 it clearly to be

seen that only in a minor number of cases it was considered unproblematic. All these cases are North American companies. The Canadian Department of Transport is explicitly mentioned for an uncomplicated working relationship. In Europe the process is mostly seen as critical. Several statements from participants worldwide say that there is a lack of understanding and sensibility for seaplane operations in the NAA.

Figure 3-15: Certification process for new seaplane operators

When asked if they were assisted with the licensing process by their NAA, North American participants generally answered that they were not, but the process was feasible and known. A Canadian operator was assisted when looking for a new aerodrome. European participants complain about the unclear regulations and a missing point of contact within EASA. Expanding the question to the expectations they have for a central certification process governed by EASA or a central institution, and which points should be included, various points were mentioned. A specific European concern is to modify EU-OPS, so that for international business, it is not necessary to study the varying national laws. Furthermore a seaplane licence rating and standardisation in issuing landing sites was prompted. One European operator wished for a distinction between commercial and private operations with respect to the level of experience.

North American participants would like to include a clear regulation about the availability of waterways. They recommend that the assessment of landing sites is done analogue to those on land with a rating for the environmental impact and designated flight and noise abatement areas. One participant states that maritime regulations should be applied for the movements on the water while aviation regulations should become effective when the aircraft becomes airborne.

Further questions were addressing specific points of contact with authorities. As to be seen in Figure 3-16, 40% of the participants are having problems with environmental authorities or residents. The reason is almost exclusively noise. In some cases in North America, participants are operating in or close to national parks.

**When starting operation, did you have problems with residents or environment authorities?**

Figure 3-16: Problems with residents or environmental authorities

More than half of the operators are affected by special regional regulations concerning the use of waterways. Besides the mentioned national parks, they face generally restricted areas, excessive diffusion of water plants or are restricted to coastal regions, as reported from Norway or the United Kingdom. One operator complains that the designated permitted areas are too small and in the wrong location for typical conditions.

When asked if the compliance with both, maritime and aviation regulations leads to a conflict, one-third thought that they do. It was stated that maritime regulations do not consider the lack of manoeuvrability and ability to come to a sudden stop when compared to a boat. In one case in Australia, the port authorities require seaplane pilots to have a recreational boat license for their commercial operations. A participant from the United Kingdom reported that the restrictions to operations the maritime authorities imposed to guarantee safety of maritime traffic were not improving the latter but reducing aviation safety.

## 4 Seaplane Organizations

Seaplane organizations are mostly associations of pilots. Although Europe is poorly represented within manufacturers and operators, there are seaplane organizations throughout the continent.

Name	City	Country	URL
Norwegian Ski- & Seaplane Association	Oslo	Norway	<a href="http://www.nak.no/sea">www.nak.no/sea</a>

Canadian Owners and Pilots Association	Ottawa	Canada	<a href="http://www.copanational.org/">www.copanational.org/</a>

Table 18: Seaplane organisations

## 5 Sea Dromes

### 5.1 General

There are two main categories of sea dromes. The first category is a sea port, where the aircraft stays seaborne. This type of sea drome usually realized with moorings, very similar to those used for sea vessels. As an example, the installation of Harbour Air in Vancouver can be seen in Figure 5-1. This kind of sea drome limits accessibility to the aircraft but allows using existing seaport infrastructure. As the aircraft does not need to be moved out of the water, very short turnaround times can be realized.

Figure 5-1: Harbour Air seadrome in Vancouver Harbour

The second category is the land-based sea port. While amphibious aircraft can leave the water autonomously on a ramp, straight seaplanes require a type of lifting mechanism. Having the aircraft turned around on land offers to integrate it into conventional processes. Also it is easily accessible and can be freed from salt water during every turnaround. Getting it out of the water anyway requires additional time and energy.

Figure 5-2: Hydroport in Gelendzhik (Anon., 2010)

## 5.2 Survey

### 5.2.1 Seaport Management

Operators were asked if they manage their seaport themselves or if their seaport is managed by other institutions. 55% of the participating seaplane/ amphibian operators were managing their seaports on their own. However, no link could be made between business size (number of aircraft operated) and seaport management. If an operator has to manage the seaport on its own seems to be dependent on the availability or the obligation to use managing services and/or special regulations varying from country to country.

### 5.2.2 Seaport License & Seaport Approval

Operators were asked which institutions issued their seaport license and/or approval. The following information could be gathered in the survey:

	Seaport License	Seaport Approval
USA	FAA, DOT (State department)	
Canada	Transport Canada	
Malta		DCA Malta
Australia	State Maritime Authority	

Table 19: Seaport Licensing Institutions

### 5.2.3 Configuration of seaside landing site

The following table gives an overview about installations currently used by seaplane operators. The use of moorings, pontoons and respective foot bridges is commonly part of a seaport. Amphibian operators need not rely on seaside infrastructure and can use land bound landing strips, of course. The use of own maintenance hangars, offices and fuel stations is also not related to business size (or aircraft operated). Additionally, the use of emergency equipment seems not to be regulated differently from country to country.

<b>Installation item</b>	<b>Operators using installation [%]</b>
Moorings / Pontoons	50%
Foot bridges	41%
Navigation lights	5%
Maintenance site/ Hangar	18%
Office	36%
Fuel Station	32%
Emergency / Fire Services	14%

Table 20: Landing site installations

Other items mentioned apart from the above list were safety boats, fuel barges and navigation marks.

### 5.2.4 Maintenance concept

According to the use of own maintenance sites/ hangars about a third of the operators use external maintenance concepts.

Figure 5-3: Maintenance concept

It was asked how many days per month the average aircraft is out of service due to maintenance. The number of days ranges from one to six days of maintenance per month. Astonishingly, aircraft which are used commonly (DHC-2 and Cessna 208) have the largest necessity for maintenance with 5 to 6 days per month not in operation. (Note: these numbers are results from the online survey and are not checked for plausibility e.g. from OEM maintenance instructions.)

#### 5.2.5 Connectivity of seaports to landside infrastructure

Table 21 shows that most operators are connected to some kind of street/ motorway infrastructure but no seaplane operator is connected to larger airports. Main business is leisure travel for most seaplane operators. Still, the option of feeding traffic into larger hub airports by amphibian aircraft is possible but not executed. About a quarter of all participating operators rely on existing seaport or airport infrastructure. However, most businesses seem to be remote locations not closely coupled to other means of transport.

Connection	% of operators
Landing site connected to roads / motorways	91%
Landing site connected to long distance railroad system	5%
Landing site connected to public metropolitan and suburban	14%
Landing site integrated in seaport	23%
Landing site connected to local airfield	23%
Landing site connected to international airport	0%

Table 21: Landside connectivity

## **6 Summary**

Summarizing the results, it seems to be clear that seaplane operation and manufacturing is well established in North America. In Europe the seaplane transport system seems to be sustained by enthusiasts. The reasons for this will be investigated in the FUSETRA project.

With the data obtained by evaluating the results of the survey as well as off the internet and the registration database, it was possible to determine the most important aircraft for seaplane transportation and how and by whom they are operated. Furthermore, information on the ground infrastructure and possible concepts for sea dromes was gathered. This is the necessary starting point for the evaluation of strengths, weaknesses, opportunities and threats to a European seaplane transportation system.

The survey provided operational data and the comments on required aircraft and necessary changes to regulations. Together with the data of the major operators this is a basis is given for the improvement of European regulation as well as for the formulation of requirements for future seaplanes.

## Appendix A – Seaplane models worldwide

Only the most important categories are displayed in the following table to keep this document clearly arranged. The complete data base contains – where available – the following information on each model:

Attribute	Attribute description
Name	Name of the aircraft
Manufacturer	Name of the manufacturer
Manufacturer Country	Country of the manufacturer
Link	URL of a photo of the aircraft
Usage	Type of mission the aircraft is mainly used for
Floats	Seplane/Flying boat, number of floats/outriggers
Wing Arrangement	High wing, low wing, mid wing, biplane
Tail	Form of the tailplane
Retractable Landing Gear	yes / no
Year of Manufacture	
Units built	
Price (\$)	
Crew	Number of crew members
Length (m)	
Span (m)	
Height (m)	
Wing Area (m <sup>2</sup> )	
MWE (kg)	Manufacturer empty weight
Payload (kg)	
MZFW (kg)	Maximum zero fuel weight
MTOW (kg)	Maximum takeoff weight
Passengers	Maximum number of passengers
Engines	Number of engines
Engine Arrangement	
Installed Power (hp)	
V <sub>max</sub> (km/h)	Maximum Speed
V <sub>cruise</sub> (km/h)	Cruise speed
Range (km)	
Flight Duration(h)	
Cruise Ceiling (m)	
Climb Rate (m/min)	
Power/Weight (hp/kg)	
Weight/Wing area (kg/m <sup>2</sup> )	
Mean Aerodynamic Chord (m)	
Aspect Ratio [-]	
Fuselage width (m)	
Engine Weight (kg)
